FNRS Postdoctoral Researcher, ULiège

Topics of interest:

- Nonlinear modal analysis
- Experimental continuation
- Vibration mitigation

Why Do We Need High-Fidelity Models?

For better decision-making capability!

Using models, we can access non measurable information (e.g., stress).

Particular operational conditions (e.g., explosions, earthquakes) that are difficult/impossible/dangerous to reproduce experimentally can be simulated.

Why Do We Need High-Fidelity Models?

But also to:

- Reduce dependence on testing (cost and time issues)
- Test design (e.g., sensor and actuator placement)
- Perform virtual prototyping:

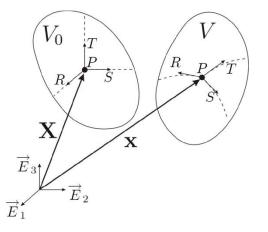

A model can predict the behavior of a structure before its construction.

The parameters of a model can easily be modified to improve the design (optimization).

1. Large displacements and rotations

Displacement: $\mathbf{u} = \mathbf{x} - \mathbf{X}$

Cauchy strain tensor:
$$\epsilon_{ij}^{C} = \frac{1}{2} \left(\frac{\partial u_i}{\partial X_j} + \frac{\partial u_j}{\partial X_i} \right)$$

Small displacements and rotations.

3. Linear structure with localized nonlinearities

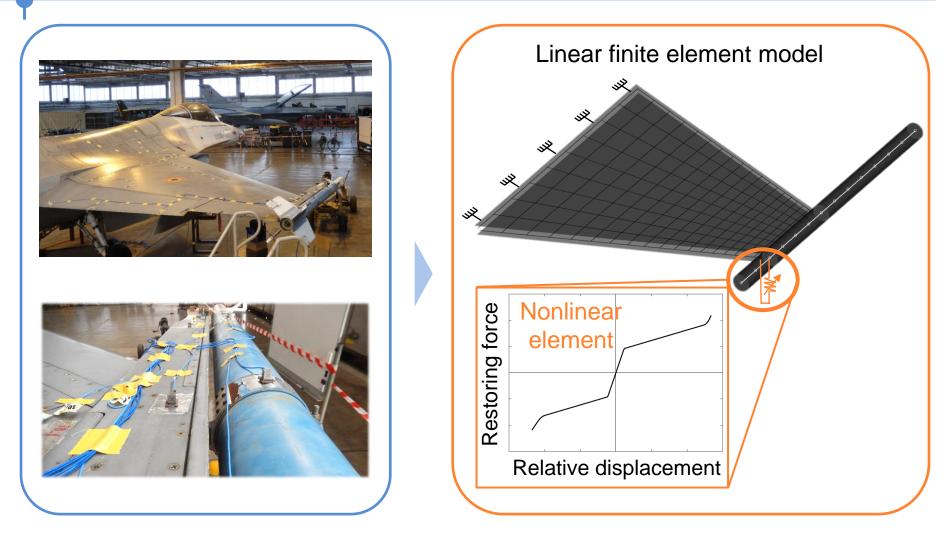

FOCUS OF THIS COURSE

High-fidelity and fast-running modeling of structures with localized nonlinearities

Integration of Data-Driven and Computer-Aided Models

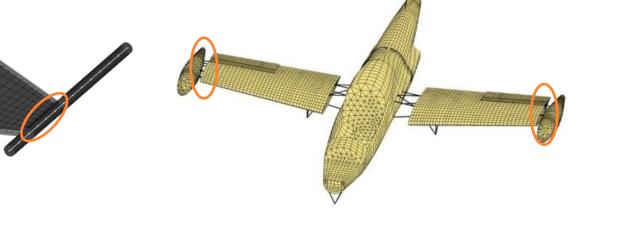

Accurate modeling of localized nonlinearities identified from experimental data (see next lectures).

Finite element models may involve thousands (even millions) of degrees of freedom (DOFs).

For structures with localized nonlinearities, only a few DOFs are generally involved in nonlinear connections.

Model reduction and substructuring can be applied to speed up simulations.

Reminders from "*Mechanical vibrations: Theory and Applications to Structural Dynamics*" (Géradin and Rixen):

Reduction: In most cases, engineers are interested in a smaller system capturing only lower frequency dynamics. In this case, a genuine reduction is performed, the reduction method being seen as a DOF economizer.

Substructuring: In the context of large projects, the analysis is frequently subdivided into several parts. A separate model is constructed for each part of the system and reduced (*super-element*). The different parts and super-elements are finally combined to simulate the dynamics of the whole system.

The original finite element model is governed by

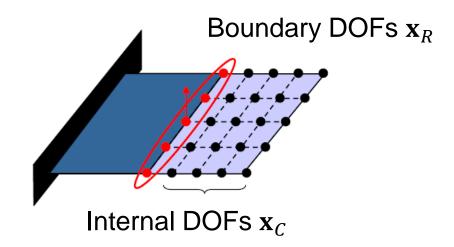

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{f}_{\text{ext}}(t)$$

Most methods for reducing the size *n* of a system consist in partitioning the degrees of freedom into n_R dynamic retained coordinates ($n_R \ll n$) and n_C condensed coordinates.

$$\mathbf{x} = \begin{bmatrix} \mathbf{X}_{R} \\ \mathbf{X}_{C} \end{bmatrix} \qquad \mathbf{K} = \begin{bmatrix} \mathbf{K}_{RR} & \mathbf{K}_{RC} \\ \mathbf{K}_{CR} & \mathbf{K}_{CC} \end{bmatrix} \qquad \mathbf{M} = \begin{bmatrix} \mathbf{M}_{RR} & \mathbf{M}_{RC} \\ \mathbf{M}_{CR} & \mathbf{M}_{CC} \end{bmatrix}$$

The dynamical behavior of the structure is usually described by the retained coordinates only.

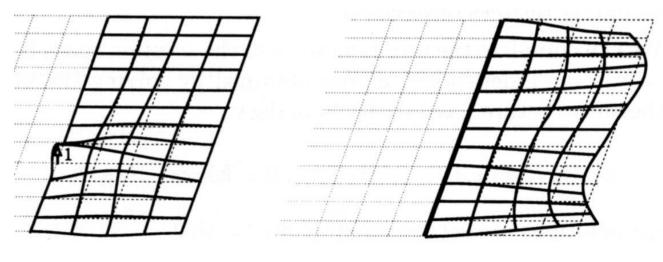

Let us consider a substructure which is connected to the rest of the system by a set of boundary degrees of freedom \mathbf{x}_R .

The originality of the method is to consider in the condensation, in addition to the boundary DOFs x_R , the contribution of the internal vibration modes to the reduced model.

The dynamical behavior of a substructure is fully described by:

- the static boundary modes resulting from the static condensation,
- the subsystem eigenmodes in clamped boundary configuration.

Static mode

Vibration mode

Accordingly, it means that the following transformation may be applied to the initial degrees of freedom:

$$\mathbf{x} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ -\mathbf{K}_{CC}^{-1}\mathbf{K}_{CR} & \mathbf{\Phi}_{C} \end{bmatrix} \begin{bmatrix} \mathbf{x}_{R} \\ \mathbf{y}_{C} \end{bmatrix} \xrightarrow{n_{R} \text{ boundary DOFs}} n_{C} \text{ intensity parameters}$$
of the internal modes

where the Guyan's reduction matrix has been complemented by the set of n_c internal vibration modes $\tilde{\mathbf{x}}$ obtained by solving:

$$(\mathbf{K}_{CC} - \widetilde{\omega}^2 \mathbf{M}_{CC}) \widetilde{\mathbf{x}} = \mathbf{0}$$
$$\mathbf{\Phi}_{C} = [\widetilde{\mathbf{X}}_{(1)} \quad \dots \quad \widetilde{\mathbf{X}}_{(n_{C})}]$$

In practice, only a certain number $m < n_c$ of internal vibration modes are kept:

$$\Phi_{\mathcal{C}} \to \Phi_m = \begin{bmatrix} \tilde{\mathbf{X}}_{(1)} & \dots & \tilde{\mathbf{X}}_{(m)} \end{bmatrix}$$
$$\mathbf{y}_{\mathcal{C}} \to \mathbf{y}_m$$

This subset of internal vibration modes should be selected in order to cover a frequency range that is large enough to approximate the dynamics in play. Convergence of the reduced-order model should be carefully assessed! Final reduction matrix of dimension $n \times (n_R + m)$:

$$\mathbf{R} = \begin{bmatrix} \mathbf{I} & \mathbf{0} \\ -\mathbf{K}_{CC}^{-1}\mathbf{K}_{CR} & \mathbf{\Phi}_{m} \end{bmatrix}$$

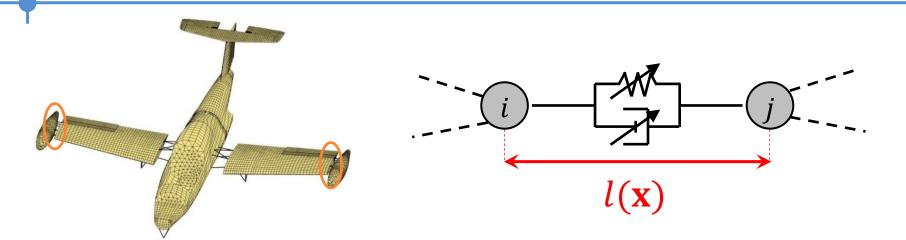

Reduced stiffness and mass matrices:

$$\overline{\mathbf{K}} = \mathbf{R}^T \mathbf{K} \mathbf{R} \qquad \overline{\mathbf{M}} = \mathbf{R}^T \mathbf{M} \mathbf{R}$$

Under the assumption of proportional damping, reduced damping matrix can be defined as

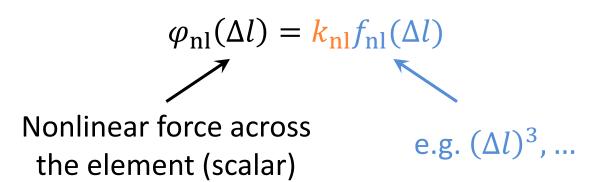

$$\overline{\mathbf{C}} = \alpha \overline{\mathbf{K}} + \beta \overline{\mathbf{M}}$$

Including Localized Nonlinearities into the Model

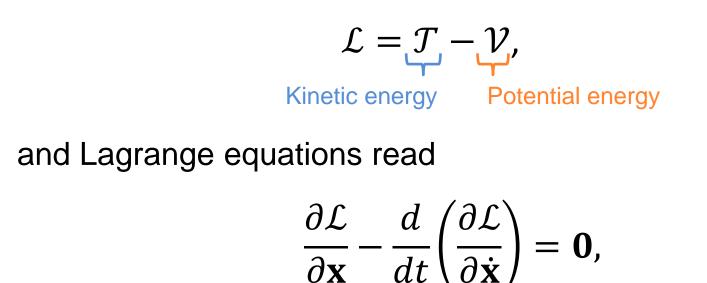

A nonlinearity is activated if it is strained ($\Delta l(\mathbf{x}) \neq 0$) $\Delta l(\mathbf{x}) = l(\mathbf{x}) - l(\mathbf{0})$

It is generally defined by a functional form and a coefficient

How to Derive the Equations of Motion?

Recall that the Lagrangian is given by

from which we can get the equations of motion.

For simplicity, we will derive them with a localized nonlinearity, in the absence of linear damping and external forcing.

Kinetic and Potential Energies of a Structure

Assuming the nonlinearity does not store kinetic energy,

$$\mathcal{T} = \frac{1}{2} \dot{\mathbf{x}}^T \mathbf{M} \dot{\mathbf{x}}$$

The potential energy is an extensive quantity

$$\mathcal{V} = \mathcal{V}_{\text{lin}} + \mathcal{V}_{\text{nl}} = \frac{1}{2}\mathbf{x}^T\mathbf{K}\mathbf{x} + \mathcal{V}_{\text{nl}}$$

and the nonlinear potential energy is given by the work of the nonlinear force

$$\mathcal{V}_{\rm nl} = \int_0^{\Delta l(\mathbf{x})} \varphi_{\rm nl}(\xi) d\xi$$

Equations of Motion

Hence,

$$\mathcal{L} = \frac{1}{2} \dot{\mathbf{x}}^T \mathbf{M} \dot{\mathbf{x}} - \frac{1}{2} \mathbf{x}^T \mathbf{K} \mathbf{x} - \int_0^{\Delta l(\mathbf{x})} \varphi_{\mathrm{nl}}(\xi) d\xi$$

Using Leibniz integral rule,

$$\frac{\partial \mathcal{L}}{\partial \mathbf{x}} - \frac{d}{dt} \left(\frac{\partial \mathcal{L}}{\partial \dot{\mathbf{x}}} \right) = -\mathbf{K}\mathbf{x} - \frac{\partial \Delta l(\mathbf{x})}{\partial \mathbf{x}} \varphi_{\mathrm{nl}}(\Delta l(\mathbf{x})) - \mathbf{M}\ddot{\mathbf{x}} = \mathbf{0}$$

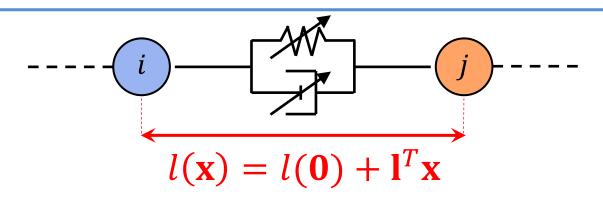

which eventually yields the equations of motion

$$\mathbf{M}\ddot{\mathbf{x}} + \mathbf{K}\mathbf{x} + \frac{\partial \Delta l(\mathbf{x})}{\partial \mathbf{x}} \varphi_{\mathrm{nl}}(\Delta l(\mathbf{x})) = \mathbf{0}$$

 $\mathbf{I}_{nl}(\mathbf{X})$

Adding other localized nonlinearities, linear damping, external forcing, ect. ... is straightforward.

Specialization to 1-Dimensional Structures

For a localized nonlinearity between DOFs i and j, the strain is simply $\partial \Lambda I$

$$\Delta l(\mathbf{x}) = \mathbf{l}^T \mathbf{x}, \qquad \frac{\partial \Delta l}{\partial \mathbf{x}} = 1$$

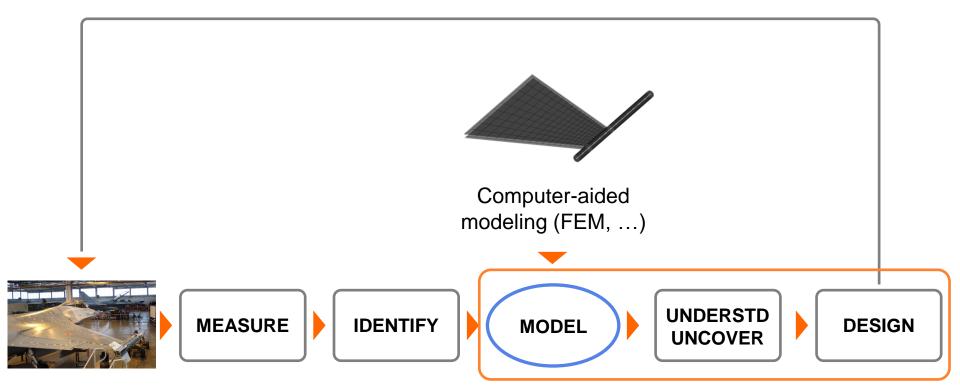

with the localization vector

$$\mathbf{l} = \begin{bmatrix} 0, \dots, 0, -1, 0, \dots, 0, 1, 0, \dots, 0 \end{bmatrix}$$
i

Thus,

$$\mathbf{M}\ddot{\mathbf{x}} + \mathbf{K}\mathbf{x} + \mathbf{l}\varphi_{\mathrm{nl}}(\mathbf{l}^{T}\mathbf{x}) = \mathbf{0}$$
$$\mathbf{f}_{\mathrm{nl}}(\mathbf{x})$$

Design Cycle of a Nonlinear Structure

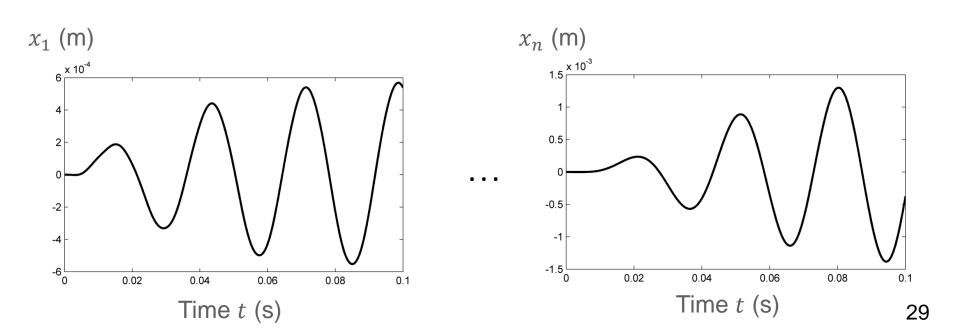

What types of simulation can be performed using a reduced-order model with localized nonlinearities?

Standard Nonlinear Simulations: Nonlinear Time Integration

Simulate the time response of a nonlinear system by solving its governing equations of motion using numerical algorithms

 $\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) + \mathbf{f}_{\mathrm{nl}}(\mathbf{x}, \dot{\mathbf{x}}) = \mathbf{f}_{\mathrm{ext}}(t)$

Time Integration Is a Simulation Standard

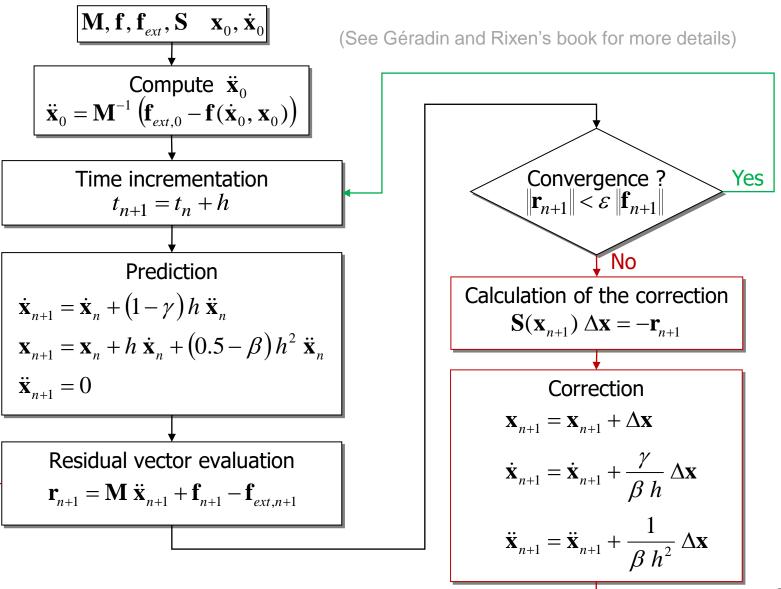

Given
$$\begin{cases} \mathsf{EOMs:} \ \mathsf{M}\ddot{\mathbf{x}}(t) + \mathsf{C}\dot{\mathbf{x}}(t) + \mathsf{K}\mathbf{x}(t) + \mathbf{f}_{\mathrm{nl}}(\mathbf{x}, \dot{\mathbf{x}}) \\ = \mathbf{f}_{\mathrm{ext}}(t) \\ \text{Initial cond.:} \ \mathbf{x}_0 = \mathbf{x}(t_0), \dot{\mathbf{x}}_0 = \dot{\mathbf{x}}(t_0) \end{cases}$$

Compute $\mathbf{x}_{n+1} = \mathbf{x}(t_{n+1})$

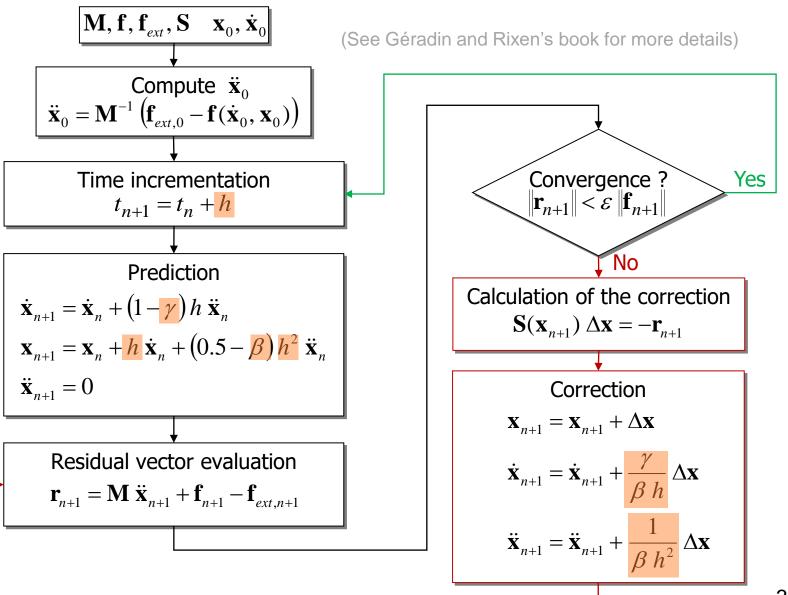

Such that
$$\mathbf{M}\ddot{\mathbf{x}}_{n+1} + \mathbf{C}\dot{\mathbf{x}}_{n+1} + \mathbf{K}\mathbf{x}_{n+1} + \mathbf{f}_{nl,n+1} = \mathbf{f}_{ext,n+1}$$

 \mathbf{f}_{n+1}

Newmark's Iterative Scheme for Nonlinear Systems

Time Step h, β and γ Are Key Parameters

Stability of Newmark's Scheme for Linear Systems

			Accuracy 人

Why Newmark and Not Runge-Kutta (ode45)?

Fixed time step

Convenient for FE models with high eigenfrequencies.

Control on stability and accuracy

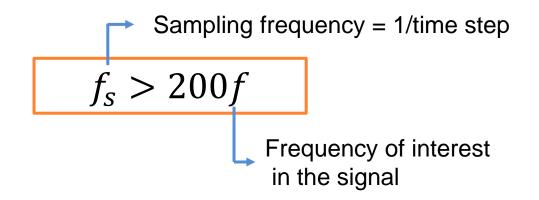

Demonstrated for linear systems with β , γ and time step h.

Possibility to add numerical damping

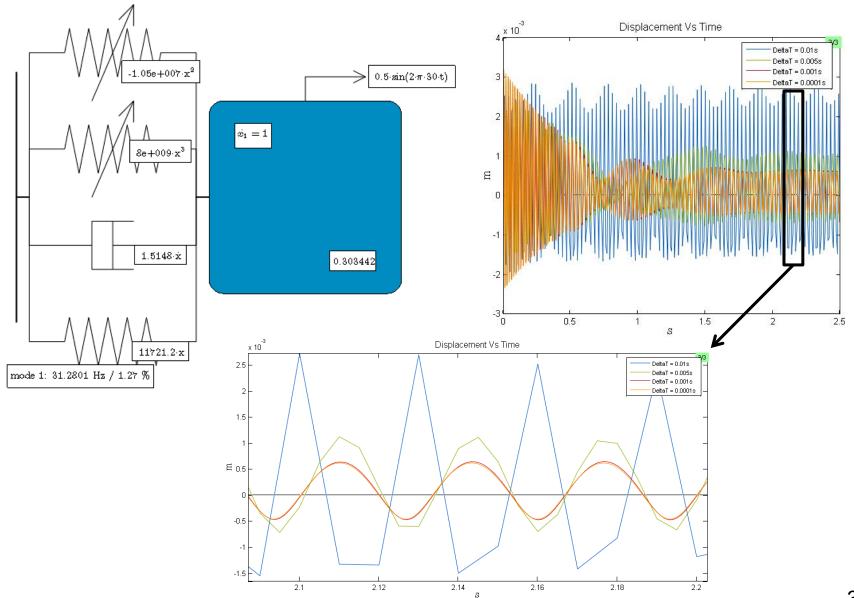

Use of the α parameter, or HHT scheme (more accurate).

Newmark's scheme is implemented in most commercial FE software.

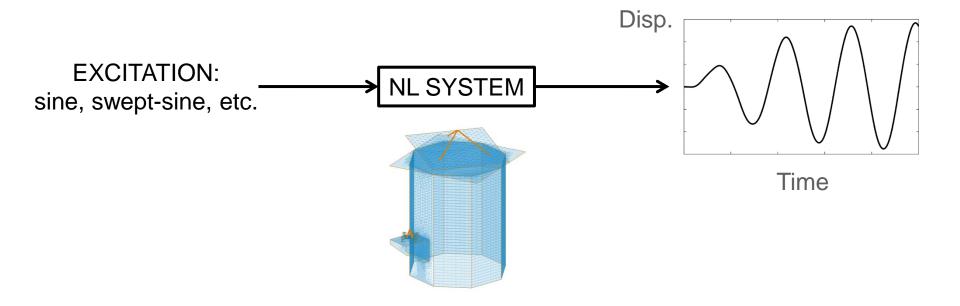

Rule of thumb: For a periodicity error of 1%, taking higher harmonics into account, consider at least

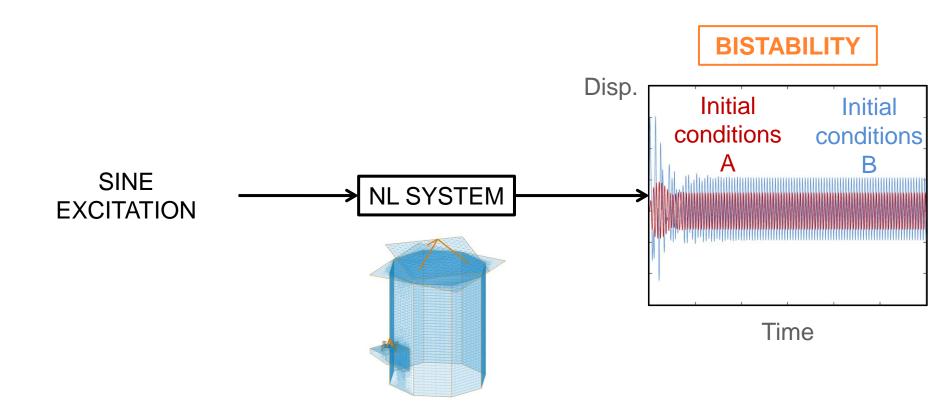

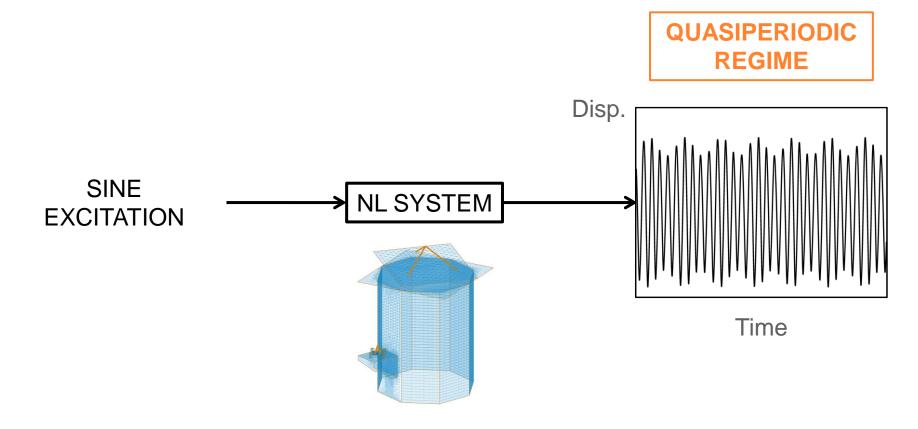

Influence of the Time Step / Sampling Frequency

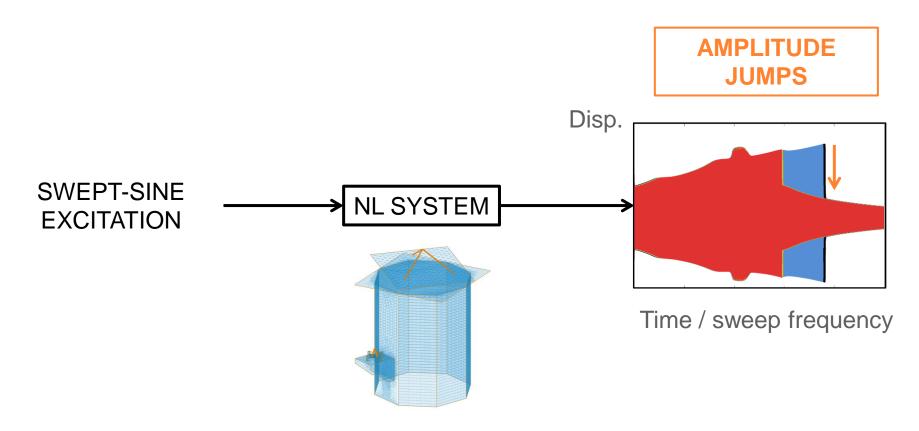

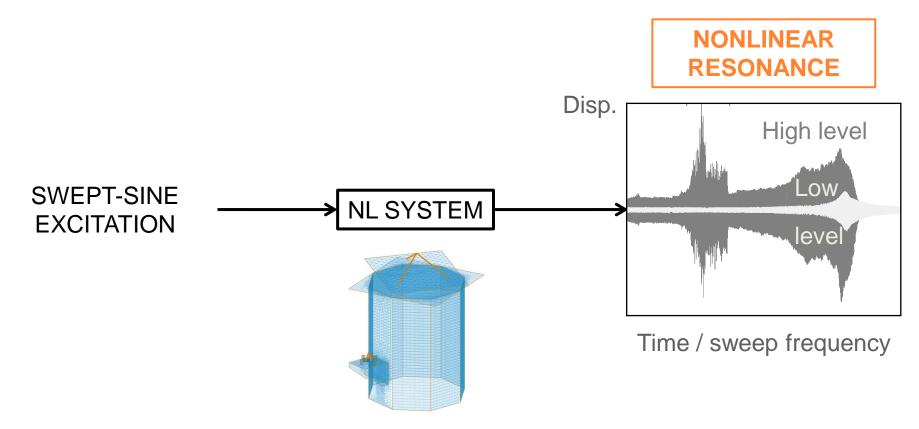

Advanced Nonlinear Simulations: Nonlinear Frequency Responses and Modes Time simulations provide useful information about structural dynamics but they can be time consuming.

NNMs are obtained by computing branches of periodic solutions of the underlying undamped and unforced model:

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) + \mathbf{f}_{nl}(\mathbf{x}) = 0$$

NNMs are useful because:

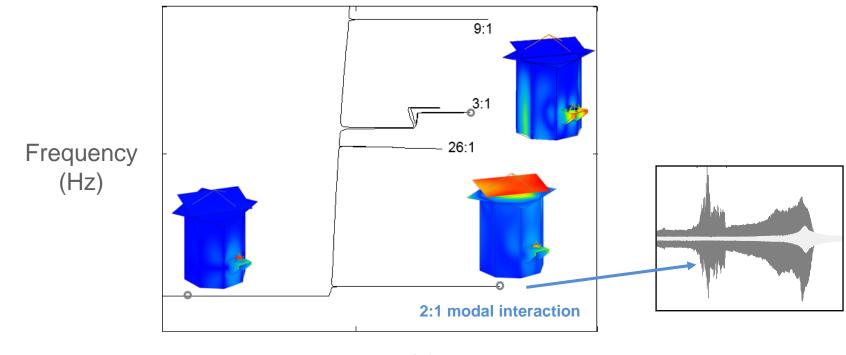

They describe the deformations at resonance of the structure.

They describe how modal parameters evolve with motion amplitude.

Nonlinear normal modes (NNMs) – See Lecture 4

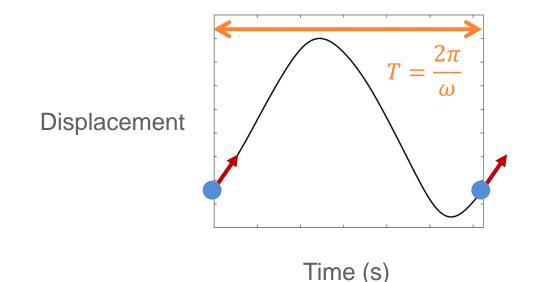

NNMs also help to uncover complex phenomena such as modal interactions / internal resonances.

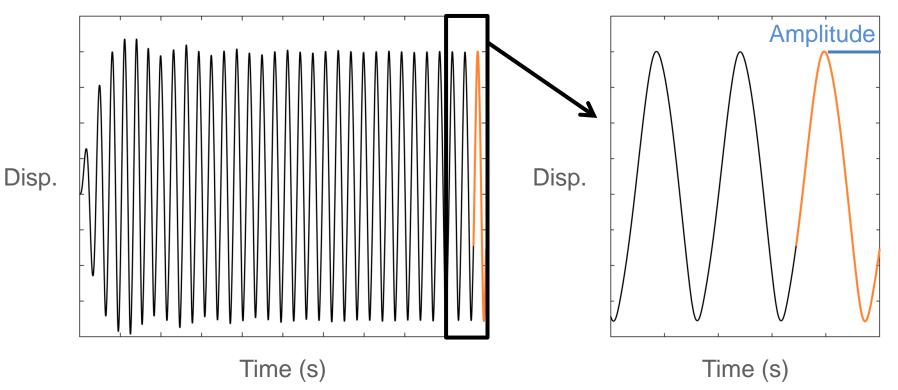

Energy (J)

NFRCs are obtained by computing branches of periodic solutions of the damped model when submitted to a harmonic excitation:

 $\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) + \mathbf{f}_{\mathrm{nl}}(\mathbf{x}, \dot{\mathbf{x}}) = \mathbf{f}_{\mathrm{ext}}(\omega, t)$

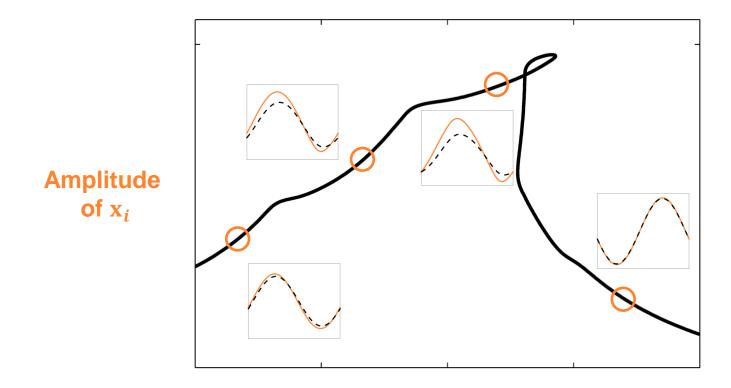

NFRCs are useful because they describe the evolution of amplitude of the steady-state responses of the structure, *i.e.*, after the transients.

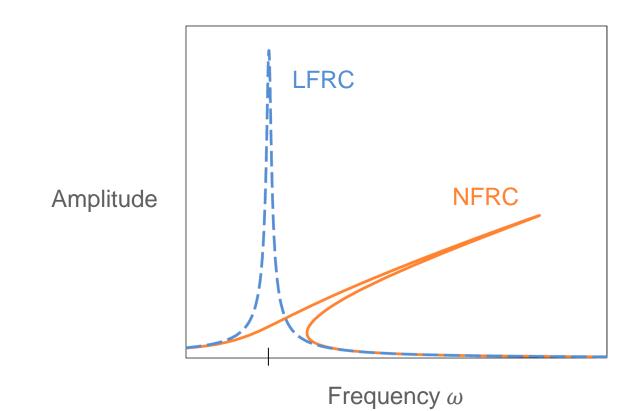

NFRCs are useful because they describe the evolution of amplitude of the steady-state responses of the structure, *i.e.*, after the transients.

The representative variable is usually chosen as the vibration amplitude of one of the DOFs, and is represented with respect to the frequency ω .

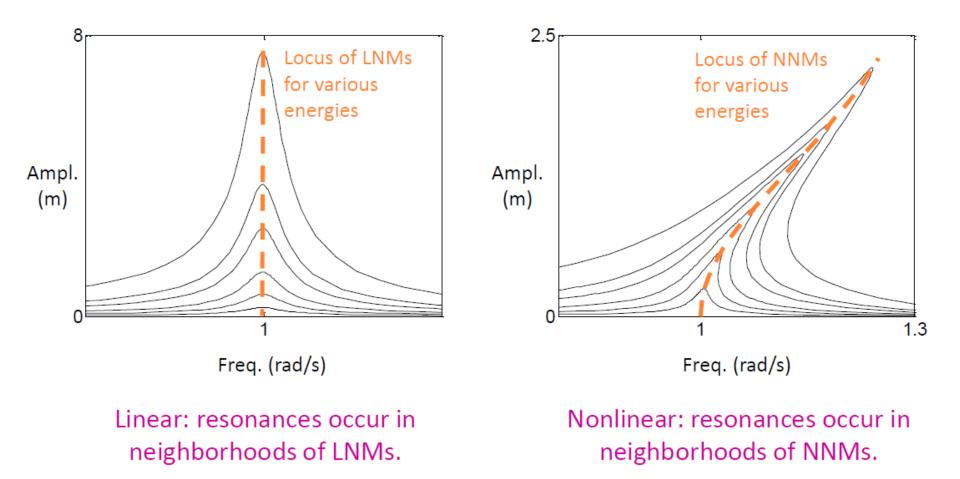

NFRCs can be seen as the nonlinear extension of linear frequency response curves (LFRCs), or FRFs.

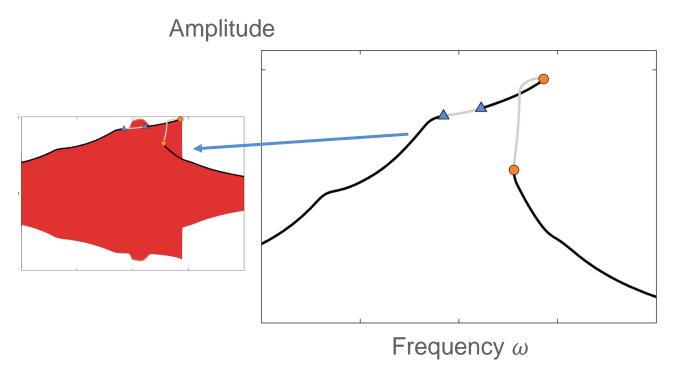

NFRCs can be seen as the nonlinear extension of linear frequency response curves (LFRCs), or FRFs.

... But

	LFRCs	NFRCs
Superposition		$\mathbf{\times}$
Uniqueness		$\mathbf{\times}$
Frequency	Energy independent	Energy dependent
Stability	Always stable	Stable or unstable

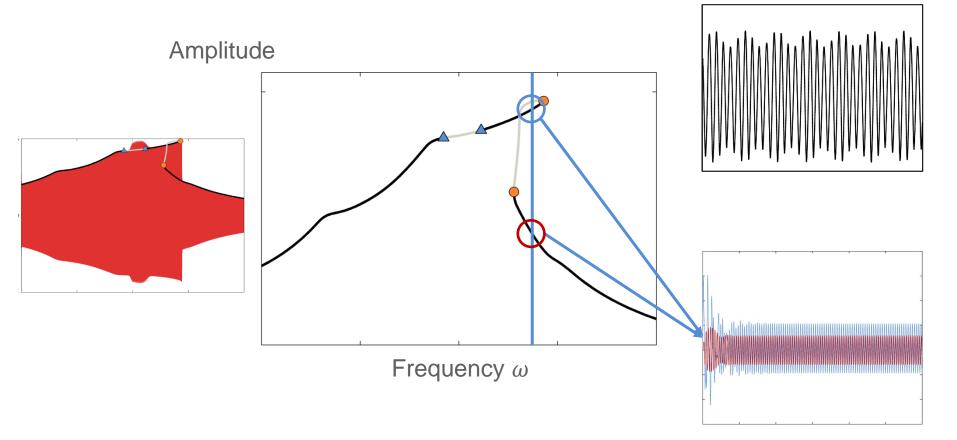

NFRCs also help to uncover complex phenomena such as amplitude jumps.

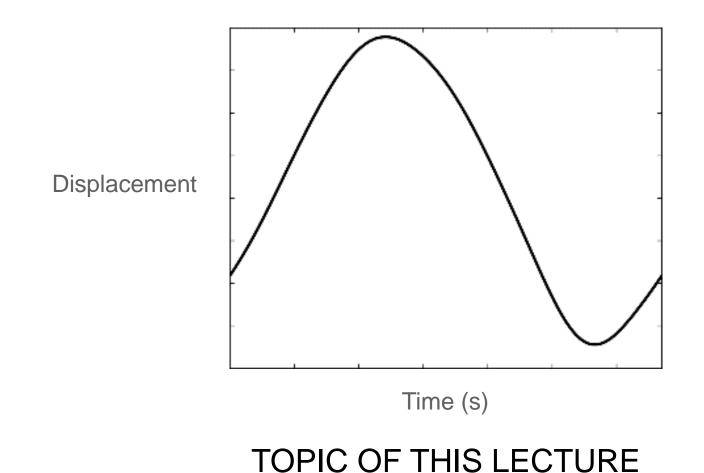

NFRCs also help to uncover complex phenomena such as quasiperiodic regime.

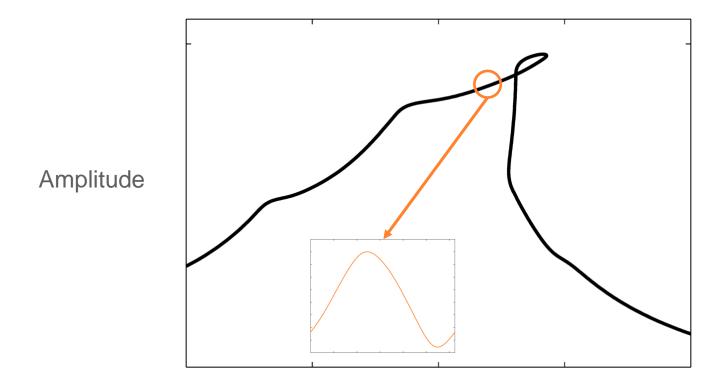

NFRCs also help to uncover complex phenomena such as bistability.

Computation of Periodic Solutions

Mathematical Representation of a Periodic Solution

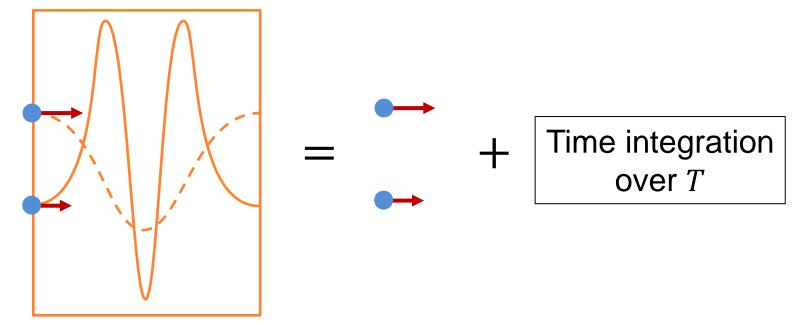

There are at least 3 approaches to describe a periodic solution.

Mathematical Representation of a Periodic Solution

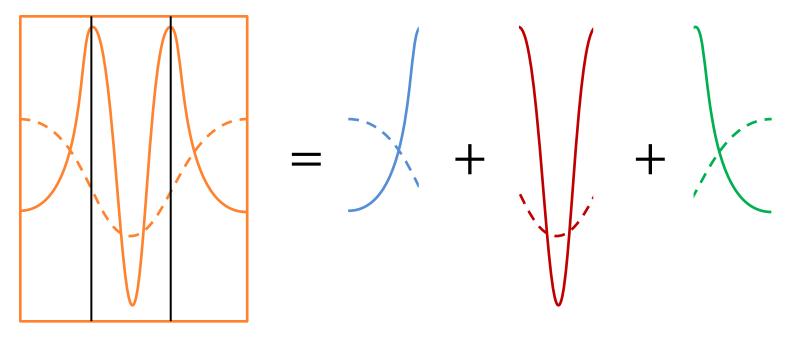

There are at least 3 approaches to describe a periodic solution.

Initial conditions $[\mathbf{x}_0 \ \dot{\mathbf{x}}_0]^T$ and the period T.

There are at least 3 approaches to describe a periodic solution.

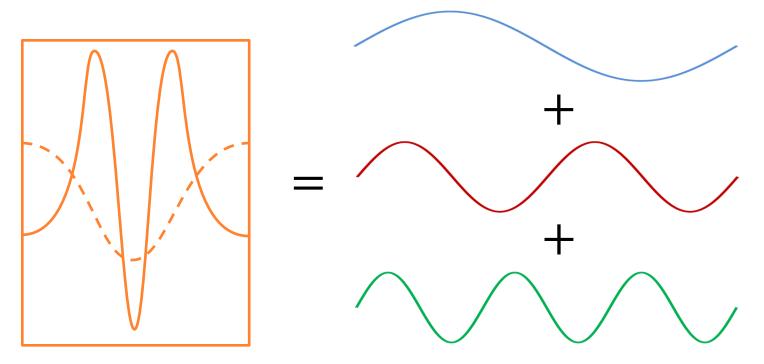

Piecewise polynomial functions and the period T.

Mathematical Representation of a Periodic Solution

There are at least 3 approaches to describe a periodic solution.

Fourier series and the period T.

Computing the periodic solution of a nonlinear system means searching for a solution \mathbf{x} that satisfies

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) + \mathbf{f}_{\mathrm{nl}}(\mathbf{x}, \dot{\mathbf{x}}) = \mathbf{f}_{\mathrm{ext}}(\omega, t)$$

with a periodicity condition

$$\mathbf{x}(t+T) = \mathbf{x}(t)$$

This represents a boundary-value problem (BVP).

Computation of a Periodic Solution

There are three approaches to solve this BVP.

Based on initial conditions $[\mathbf{x}_0 \ \dot{\mathbf{x}}_0]^T$.

Shooting technique

Based on piecewise polynomial functions.

Orthogonal collocation (not discussed here)

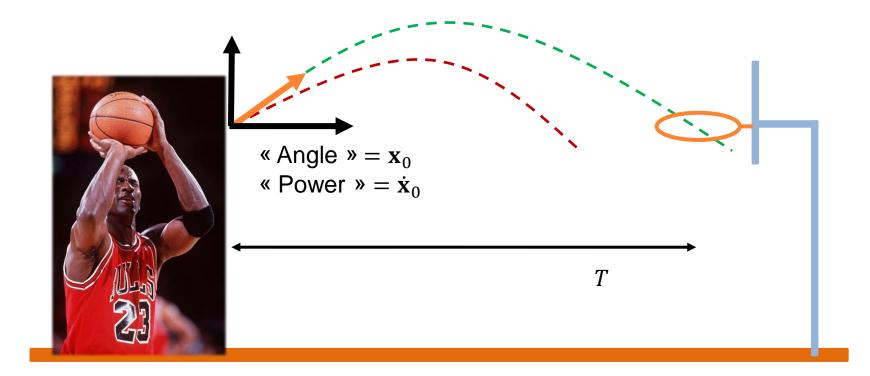

Based on Fourier series.

Harmonic balance method

Shooting Technique

Optimization of the initial state of a system $[\mathbf{x}_0 \ \dot{\mathbf{x}}_0]^T$ to obtain a periodic solution after time integration over a period *T*.

The equations of motion are first recast in state-space form:

$$\dot{\mathbf{y}}(t) = \mathbf{L}\mathbf{y}(t) - \mathbf{g}_{\mathrm{nl}}(\mathbf{y}) + \mathbf{g}_{\mathrm{ext}}(\omega, t)$$

with

g

$$\mathbf{y} = \begin{bmatrix} \mathbf{x} \\ \dot{\mathbf{x}} \end{bmatrix} \qquad \mathbf{L} = \begin{bmatrix} \mathbf{0} & \mathbf{I}_n \\ -\mathbf{M}^{-1}\mathbf{K} & -\mathbf{M}^{-1}\mathbf{C} \end{bmatrix}$$
$$\mathbf{g}_{ext} = \begin{bmatrix} \mathbf{0} \\ \mathbf{M}^{-1}\mathbf{f}_{ext}(\omega, t) \end{bmatrix}$$

The state of this system at time *t* and given initial condition y_0 is denoted as $y = y(t; y_0)$.

An initial state $\mathbf{y}_{0,p}$ leads to a periodic solution if

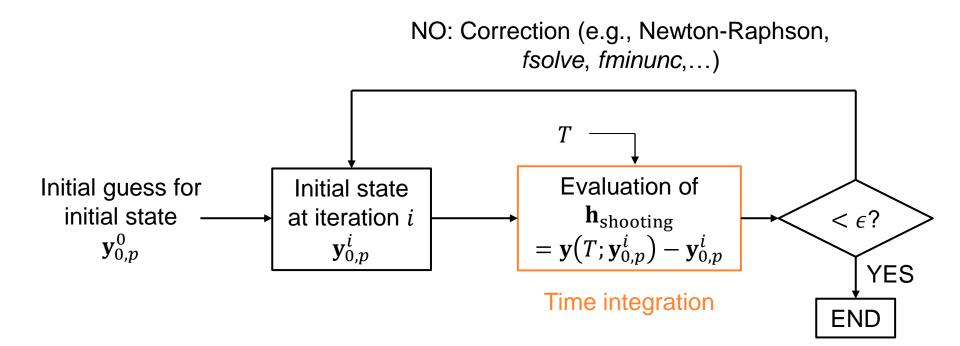

$$\mathbf{h}_{\text{shooting}} \equiv \mathbf{y}(T; \mathbf{y}_{0,p}) - \mathbf{y}_{0,p} = \mathbf{0}$$

where $\mathbf{y}(T; \mathbf{y}_{0,p})$ is computed from time integration of the EOMs.

The shooting technique consists in computing $\mathbf{y}_{0,p}$ that satisfies $\mathbf{h}_{\text{shooting}} = \mathbf{0}$ for *T* known a priori (NFRC) or not (NNM).

In the case of a harmonic excitation with frequency ω , $T = 2\pi/\omega$.

Shooting Technique Scheme (for NFRCs)

The shooting technique is efficient and accurate for small nonlinear systems (1-30 DOFs).

For larger systems however, demand in CPU time (multiple time integrations) and memory space can be problematic.

For such cases, one usually relies on the harmonic balance method.

$$\begin{aligned} \mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) &= \mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t) \\ &= \mathbf{f}_{\text{ext}}(\omega, t) - \mathbf{f}_{\text{nl}}(\mathbf{x}, \dot{\mathbf{x}}) \end{aligned}$$

where $f(x, \dot{x}, \omega, t)$ gathers both nonlinear and external forces.

The harmonic balance (HB) method consists in approximating the displacements $\mathbf{x}(t)$ with Fourier series truncated to the order N_H .

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t)$$
$$\mathbf{x}(t) = \frac{\mathbf{C}_0^{\mathbf{x}}}{\sqrt{2}} + \sum_{k=1}^{N_H} (\mathbf{s}_k^{\mathbf{x}} \sin(k\omega t) + \mathbf{c}_k^{\mathbf{x}} \cos(k\omega t))$$

The new unknowns are the Fourier coefficients z, with

$$\mathbf{z} = \begin{bmatrix} \mathbf{c}_0^{\mathbf{x}T} & \mathbf{s}_1^{\mathbf{x}T} & \mathbf{c}_1^{\mathbf{x}T} & \dots & \mathbf{s}_{N_H}^{\mathbf{x}} & \mathbf{c}_{N_H}^{\mathbf{x}} \end{bmatrix}^T$$
$$n_Z = n(2N_H + 1) \text{ unknowns}$$

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t)$$
$$\mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t) = \frac{\mathbf{c}_0^{\mathbf{f}}}{\sqrt{2}} + \sum_{k=1}^{N_H} (\mathbf{s}_k^{\mathbf{f}} \sin(k\omega t) + \mathbf{c}_k^{\mathbf{f}} \cos(k\omega t))$$

The Fourier coefficients of f are denoted by b, with

$$\mathbf{b} = \begin{bmatrix} \mathbf{c}_0^{\mathbf{f}^T} & \mathbf{s}_1^{\mathbf{f}^T} & \mathbf{c}_1^{\mathbf{f}^T} & \dots & \mathbf{s}_{N_H}^{\mathbf{f}^T} & \mathbf{c}_{N_H}^{\mathbf{f}^T} \end{bmatrix}^T$$
$$= \mathbf{b}(\mathbf{z}) \text{ since } \mathbf{f} \text{ depends on } \mathbf{x}.$$

Displacements and forces can be recast into a more compact form

$$\mathbf{x}(t) = (\mathbf{Q}(t) \otimes \mathbf{I}_n)\mathbf{z}$$
$$\mathbf{f}(t) = (\mathbf{Q}(t) \otimes \mathbf{I}_n)\mathbf{b}$$

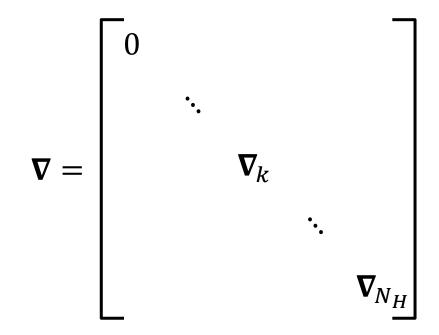

where \otimes denotes the Kronecker tensor product, I_n represents the identity matrix and where Q(t) is the orthogonal trigonometric basis:

$$\mathbf{Q}(t) = \begin{bmatrix} \frac{1}{\sqrt{2}} & \sin(\omega t) & \cos(\omega t) & \dots & \sin(N_H \omega t) & \cos(N_H \omega t) \end{bmatrix}$$

With this formulation, velocities can also be defined using Fourier series:

$$\dot{\mathbf{x}}(t) = \left(\dot{\mathbf{Q}}(t) \otimes \mathbf{I}_n\right) \mathbf{z} = \left(\left(\mathbf{Q}(t)\mathbf{\nabla}\right) \otimes \mathbf{I}_n\right) \mathbf{z}$$

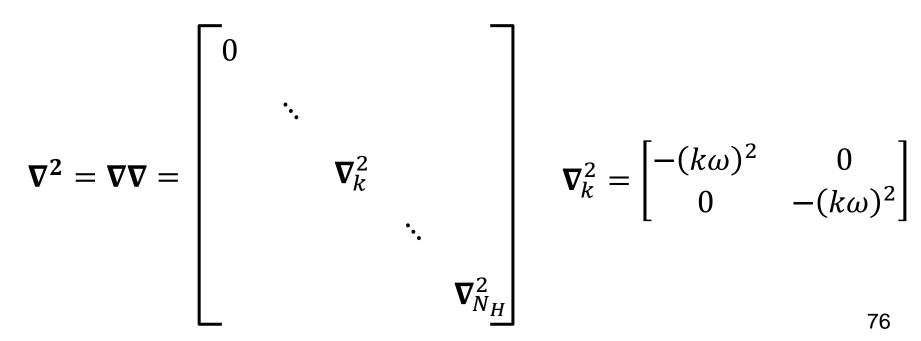

$$\mathbf{\nabla}_{k} = \begin{bmatrix} 0 & -k\omega \\ k\omega & 0 \end{bmatrix}$$

With this formulation, accelerations can also be defined using Fourier series:

$$\ddot{\mathbf{x}}(t) = \left(\ddot{\mathbf{Q}}(t) \otimes \mathbf{I}_n\right) \mathbf{z} = \left(\left(\mathbf{Q}(t) \nabla^2\right) \otimes \mathbf{I}_n\right) \mathbf{z}$$

where

$$\mathbf{M}\ddot{\mathbf{x}}(t) + \mathbf{C}\dot{\mathbf{x}}(t) + \mathbf{K}\mathbf{x}(t) = \mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t)$$

Fourier series approximation

$\mathbf{M} \big((\mathbf{Q}(t) \nabla^2) \otimes \mathbf{I}_n \big) \mathbf{z} + \mathbf{C} \big((\mathbf{Q}(t) \nabla) \otimes \mathbf{I}_n \big) \mathbf{z} \\ + \mathbf{K} (\mathbf{Q}(t) \otimes \mathbf{I}_n) \mathbf{z} = (\mathbf{Q}(t) \otimes \mathbf{I}_n) \mathbf{b}$

This expression can be further simplified using:

- Galerkin procedure (to remove time dependency).
- Kronecker product properties.

In a more compact form:

$$\mathbf{h}(\mathbf{z},\omega) \equiv \mathbf{A}(\omega)\mathbf{z} - \mathbf{b}(\mathbf{z}) = \mathbf{0}$$

where A describes the linear dynamics

$$\mathbf{A} = \nabla^{2} \otimes \mathbf{M} + \nabla \otimes \mathbf{C} + \mathbf{I}_{2N_{H}+1} \otimes \mathbf{K}$$

$$\mathbf{K}$$

$$\mathbf{K} - \omega^{2}\mathbf{M} - \omega\mathbf{C}$$

$$\omega\mathbf{C} \quad \mathbf{K} - \omega^{2}\mathbf{M}$$

$$\ddots$$

$$\mathbf{K} - (N_{H}\omega)^{2}\mathbf{M} - N_{H}\omega\mathbf{C}$$

$$N_{H}\omega\mathbf{C} \quad \mathbf{K} - (N_{H}\omega)^{2}\mathbf{M}$$

In a more compact form:

$$\mathbf{h}(\mathbf{z},\omega) \equiv \mathbf{A}(\omega)\mathbf{z} - \mathbf{b}(\mathbf{z}) = \mathbf{0}$$

where **b** is the Fourier coefficients vector of nonlinear and external forces

$$\mathbf{f}(\mathbf{x}, \dot{\mathbf{x}}, \omega, t) = \mathbf{f}_{\text{ext}}(\omega, t) - \mathbf{f}_{\text{nl}}(\mathbf{x}, \dot{\mathbf{x}})$$
$$= \frac{\mathbf{c}_0^{\mathbf{f}}}{\sqrt{2}} + \sum_{k=1}^{N_H} \left(\mathbf{s}_k^{\mathbf{f}} \sin(k\omega t) + \mathbf{c}_k^{\mathbf{f}} \cos(k\omega t) \right)$$

$$\mathbf{b} = \begin{bmatrix} \mathbf{c}_0^{\mathbf{f}^T} & \mathbf{s}_1^{\mathbf{f}^T} & \mathbf{c}_1^{\mathbf{f}^T} & \dots & \mathbf{s}_{N_H}^{\mathbf{f}^T} & \mathbf{c}_{N_H}^{\mathbf{f}^T} \end{bmatrix}^T$$

b can be computed, e.g., with an alternating frequency-time scheme, since the evaluation of the nonlinear forces in the time domain is straightforward.

In a more compact form:

$$\mathbf{h}(\mathbf{z},\omega) \equiv \mathbf{A}(\omega)\mathbf{z} - \mathbf{b}(\mathbf{z}) = \mathbf{0}$$

If for a given forcing frequency ω , one finds a vector \mathbf{z}^* such that

$$\mathbf{h}(\mathbf{z}^*,\omega) = \mathbf{0}$$

Then the time series $\mathbf{x}^*(t)$ reconstructed from \mathbf{z}^*

$$\mathbf{h}(\mathbf{z},\omega) \equiv \mathbf{A}(\omega)\mathbf{z} - \mathbf{b}(\mathbf{z}) = \mathbf{0}$$

 $h(z, \omega) = 0$ is a nonlinear algebraic equation (easier to solve than time integrations as in shooting technique).

z are the Fourier coefficients of the displacements and the new unknowns of the problem (usually less than for orthogonal collocation).

For NFRCs, ω is the forcing frequency and is a system parameter.

Scaling factor for time:	3000	
Apply		Cancel

Because the frequency (e.g., 30Hz = 188rad/s) and the amplitude (e.g., 0.001m) have different orders of magnitude,
time and displacements have to be rescaled to avoid ill conditioning.

Harmonic Balance Method: In Summary

PROS	CONS
Efficient	Less accurate
Harmonic coefficients available	Many harmonics are sometimes required
Filtering	

Adaptations of the method improve its performance (chain rule, ...) – not discussed here.

Periodic solutions of nonlinear structures can be computed with time-domain (shooting, orthogonal collocation) or frequency-domain method (harmonic balance).

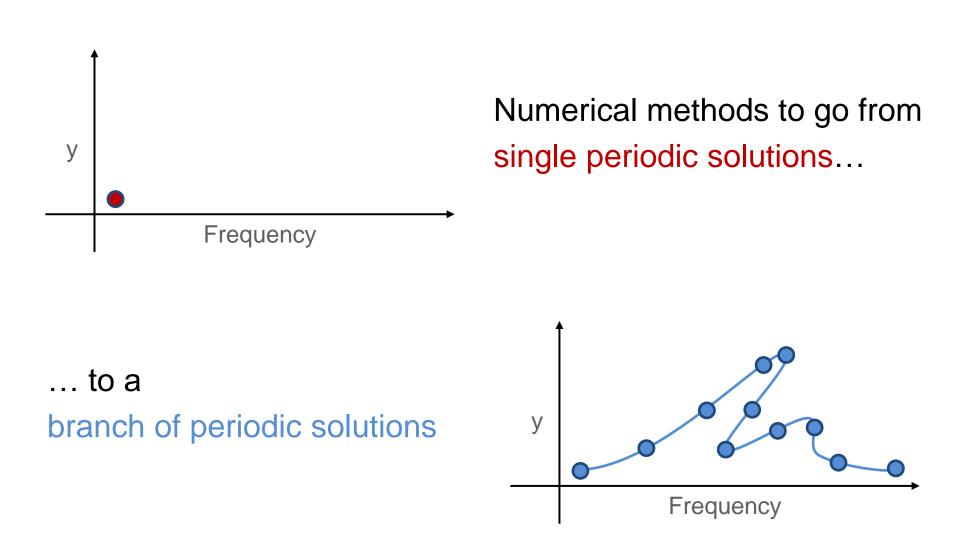

The differences between these methods lie in their accuracy and execution time.

Without adaptation, however, the harmonic balance:

- Fails at computing periodic reponses in severe nonlinear regimes (need for continuation procedure).
- Does not indicate if the solutions can be observed experimentally or not (need for a stability analysis).

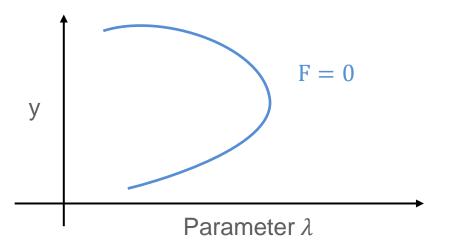

Computation of Branches of Periodic Solutions

Computation of Branches of Periodic Solutions

Mathematical Definition of a Branch of Periodic Solutions

Let us consider a function $F: \mathbb{R}^{n+1} \to \mathbb{R}^n$. A branch is a set of solutions $F(x, \lambda) = 0$, where x are the state variables and λ is a system parameter.

The branch can be represented in a 2D plane through the evolution of a representative variable $y = y(\mathbf{x})$ w.r.t. λ .

(For a more formal definition, see the implicit function theorem.)

In this course, the branch is composed by solutions of the harmonic balance equation for a nonlinear system:

h(**z**,
$$\omega$$
): $\mathbb{R}^{n_z+1} \to \mathbb{R}^{n_z}$
→ Frequency (= system parameter)
→ Fourier coefficients (= state variables)

Nonlinear Frequency Response Curves

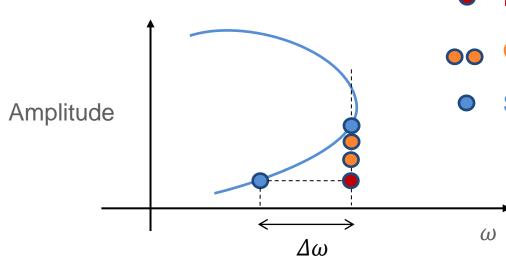

Forced and damped system

Unforced and undamped system

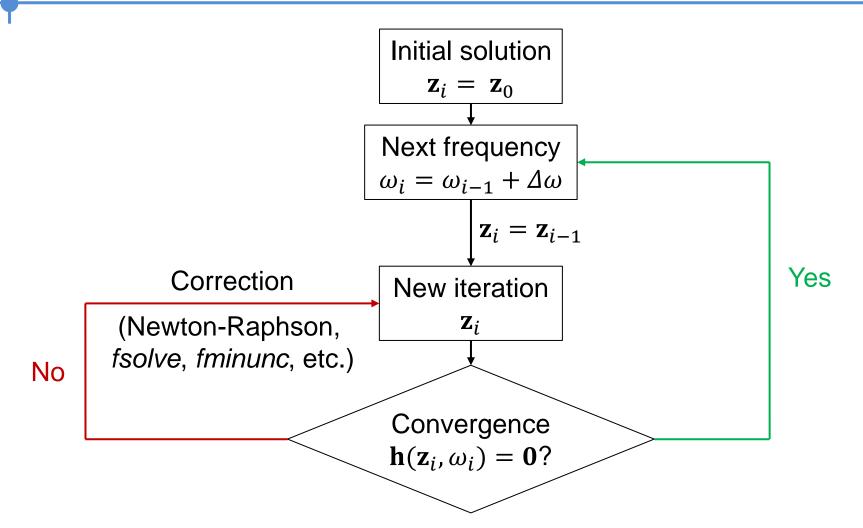

Sequential Continuation – A Straightforward Approach

Increase the period and use the previously computed periodic solution as an initial guess for the next computation.

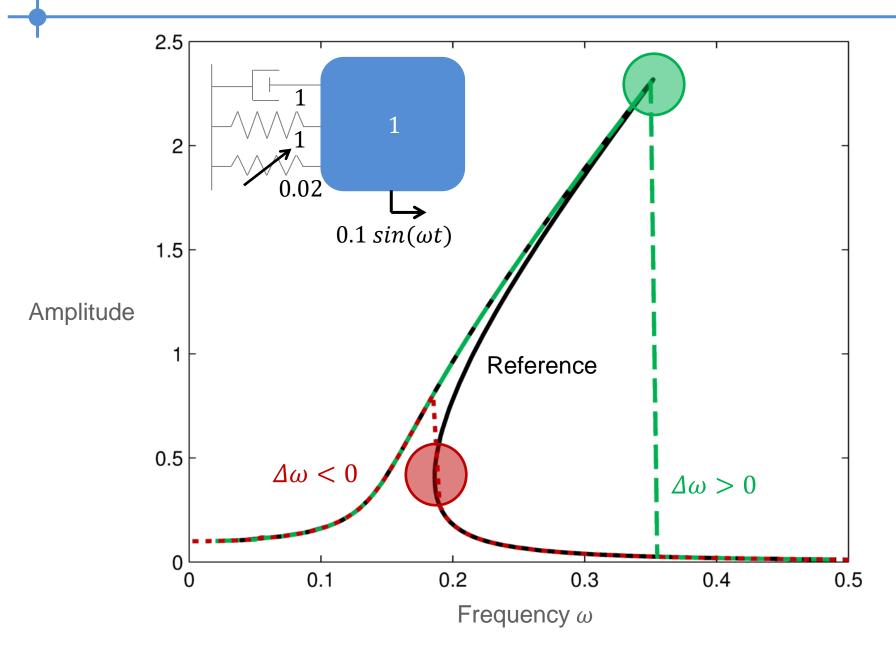

- Previous solution as prediction
- Optimization with fixed frequency
- Solutions of the branch

Sequential Continuation – Scheme

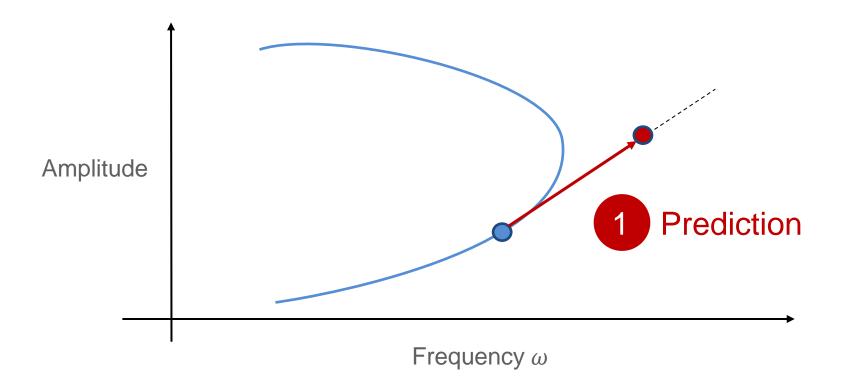

If HB method is already implemented, sequential continuation is programmed in a few lines.

Sequential Continuation Fails at Turning Points

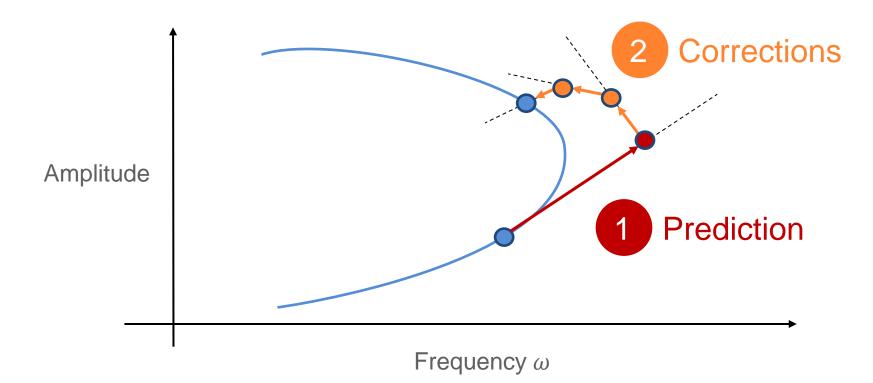

A New Continuation Scheme

In order to pass through turning points, both the state z and the parameter ω should vary. This is done through a 2-step procedure:

A New Continuation Scheme

In order to pass through turning points, both the state z and the parameter ω should vary. This is done through a 2-step procedure:

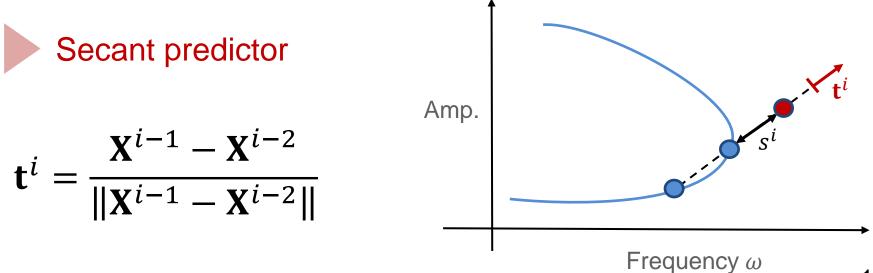

Different predictors can be considered:

$$\mathbf{X}_{\text{pred}}^{i} = \mathbf{X}^{i-1} + s^{i} \mathbf{t}^{i}$$

$$\bigcup \quad \text{Unit vector}$$

$$\longrightarrow \text{Stepsize}$$

where $\mathbf{X} = [\mathbf{z} \ \omega]^T$ denotes the unknown vector.

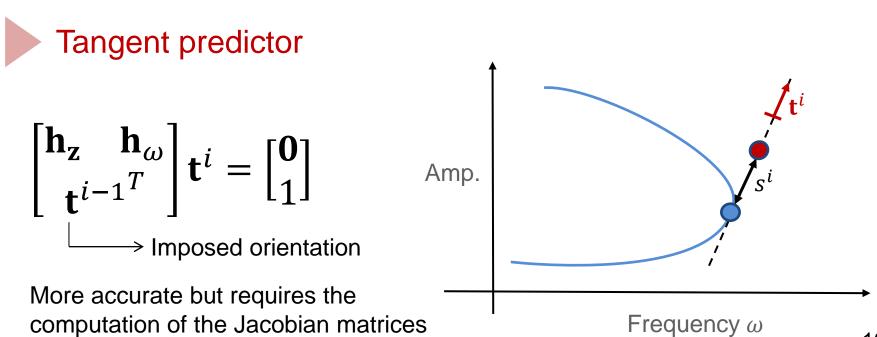

Predictor Step

Different predictors can be considered:

$$\mathbf{X}_{pred}^{i} = \mathbf{X}^{i-1} + s^{i} \mathbf{t}^{i}$$

$$\bigcup \text{Unit vector}$$

$$\longrightarrow \text{Stepsize}$$

We are looking for a solution of $h(z, \omega) = 0$, with

$$\mathbf{h}(\mathbf{z}, \omega) : \mathbb{R}^{n_z + 1} \to \mathbb{R}^{n_z}$$

Two possibilities:

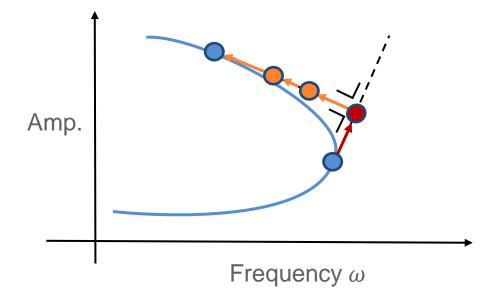

Fix the parameter ω and only optimize z.

Cf. sequential continuation

Add another equation to the system.

Pseudo-arclength and Moore-Penrose schemes

With the pseudo-arclength scheme, a solution is sought in the perpendicular direction w.r.t. the prediction.

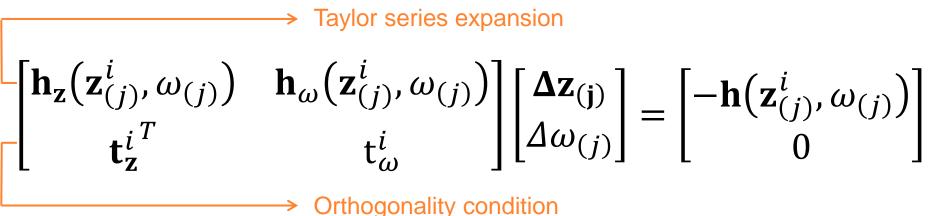

With the pseudo-arclength scheme, a solution is sought in the perpendicular direction w.r.t. the prediction.

$$\mathbf{z}_{(j+1)}^{i} = \mathbf{z}_{(j)}^{i} + \Delta \mathbf{z}_{(j)}$$
$$\omega_{(j+1)}^{i} = \omega_{(j)}^{i} + \Delta \omega_{(j)}$$

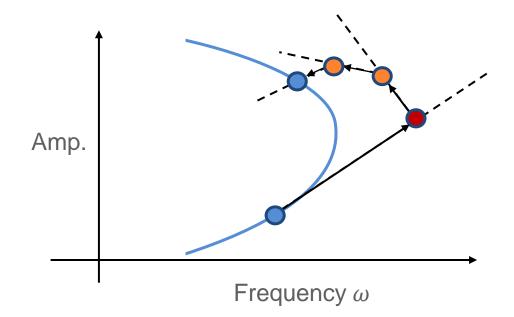

i =continuation iteration (j) =corrector iteration

with

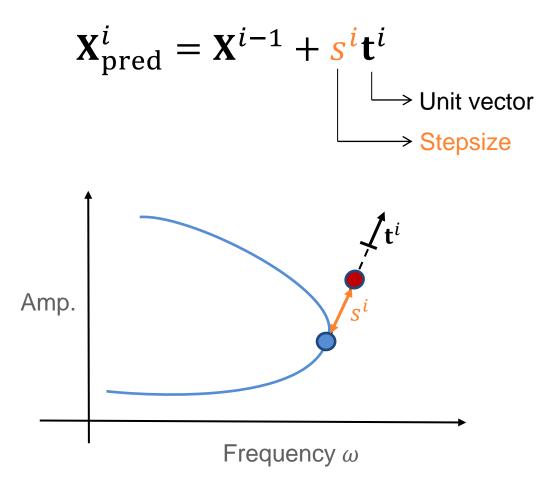

Other corrector definitions can also be used.

With the Moore-Penrose scheme for instance, the correction direction is updated at each corrector step.

Stepsize is a key parameter for the continuation procedure.

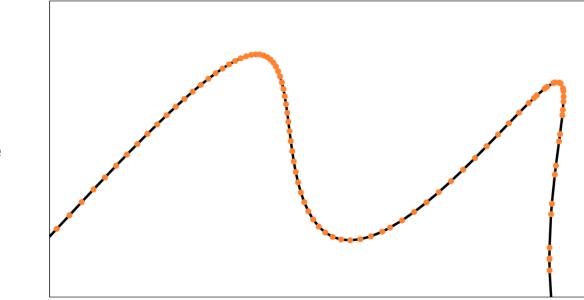

Small Stepsize

Small number of corrections

Good resolution for the branch

Slow continuation procedure

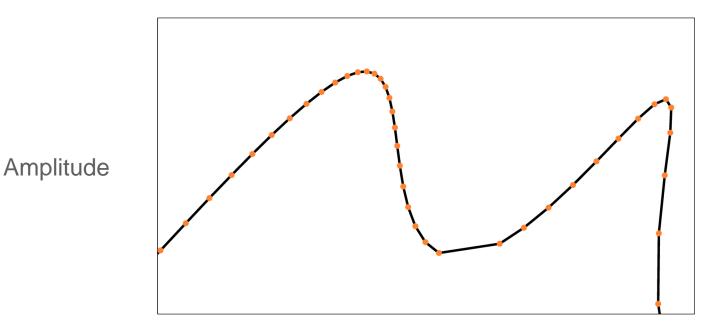

Frequency ω

Amplitude

Large Stepsize

- Large number of corrections
- Poor resolution for the branch

Frequency ω

Stepsize Strategy

Fixed stepsize

$$s^i = \text{constant}$$

$$s^{i} = \frac{M^{*}}{M}s^{i-1}$$

where M is the iteration number for the current correction, and M^* is the optimal iteration number. With the harmonic balance method, the displacements are approximated with Fourier series.

Number of harmonics

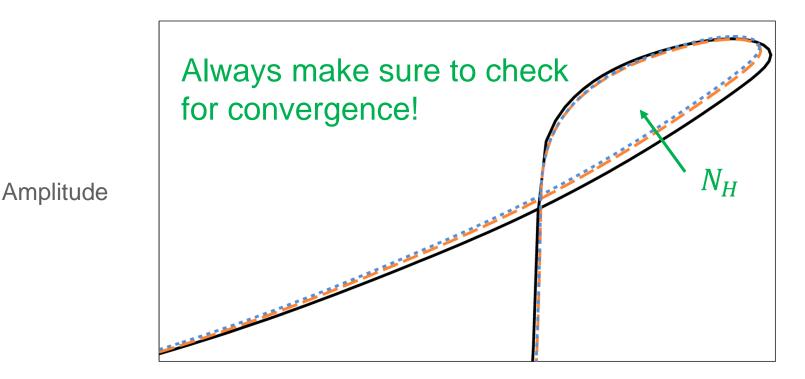

$$\mathbf{x}(t) = \mathbf{c}_{0}^{\mathbf{X}} + \sum_{k=1}^{N_{H}} (\mathbf{s}_{k}^{\mathbf{X}} \sin(k\omega t) + \mathbf{c}_{k}^{\mathbf{X}} \cos(k\omega t))$$

Fourier coefficients z are computed with the discrete Fourier transform:

$$\mathbf{z} = \mathbf{\Gamma}^+(\mathbf{N})\tilde{\mathbf{x}}$$

Number of time samples (power of 2)

 N_H has a direct influence on the accuracy of the harmonic balance solution, and hence on the accuracy of the branch.

Frequency ω

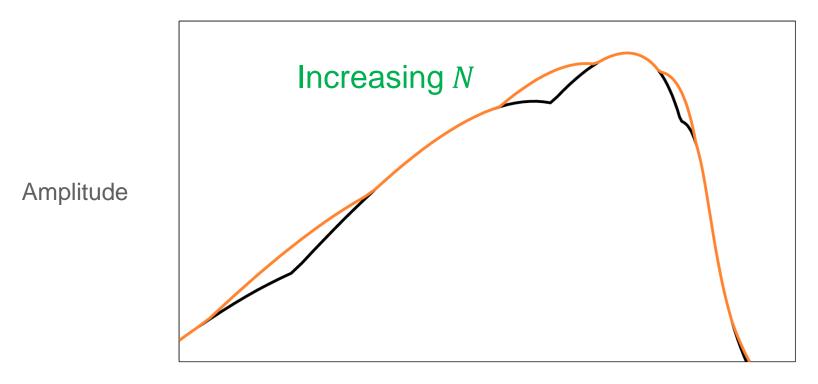

Influence of the Number of Time Samples *N*

N has a direct influence on the discrete Fourier transform, and the accuracy of the alternating frequency/time-domain method.

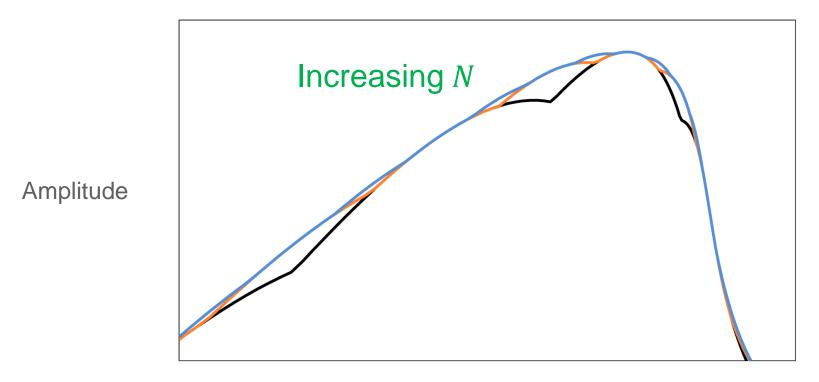

Influence of the Number of Time Samples N

N has a direct influence on the discrete Fourier transform, and the accuracy of the alternating frequency/time-domain method.

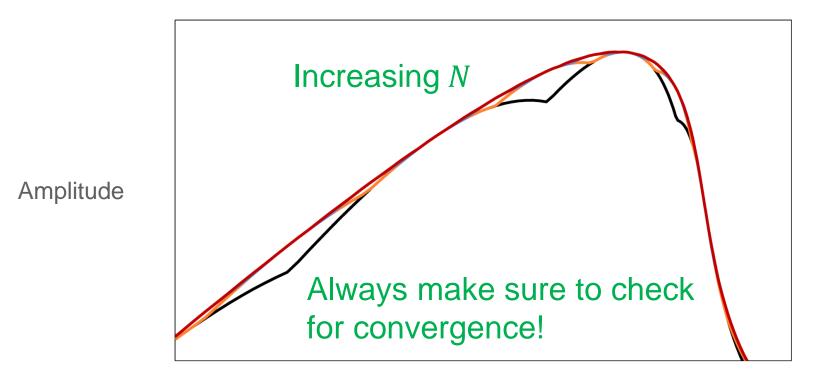

Influence of the Number of Time Samples N

N has a direct influence on the discrete Fourier transform, and the accuracy of the alternating frequency/time-domain method.

Frequency ω

N has a direct influence on the discrete Fourier transform, and the accuracy of the alternating frequency/time-domain method.

Sequential continuation can be easily implemented to represent the evolution of the periodic solutions w.r.t. to the frequency ω but it fails at turning points.

Continuation schemes based on predictor/corrector steps give the evolution of the periodic solutions in both stable and unstable regions.

HB and continuation parameters have to be carefully selected to ensure accuracy and good resolution of the branches.
